Final Project: Pick a Project

Computer Science - Week 10

Oct 3, 2026 - Version 0.0.2

Please make sure to your UD **email** AND **name** is below. Unless your UD emails are included in this table, then you will not earn any points for this assignment when it is graded! **Every person should submit their own individual worksheet**.

Talk about each of the questions with a friend or our LLM (or both), but **make sure the words you enter below are yours** (with the obvious exceptions notwithstanding). Brainstorming is best done in full sentences, and the main goal here is brainstorming. It's worth reviewing the information in this series of pages in the Drafter documentation to gain a better understanding of the process.

Role	Name	Email
Developer (You)	Jemuel Picol	jemuel@udel.edu
Friend (optional)		

Part 1: The Goal & Prior Implementations

1. **Identify the Goal:** What specific goal are you trying to address? Think about your passions, hobbies, and academic interests. The latter are an excellent candidate to focus on. Some majors have suggestions listed below: these were provided by faculty in those departments. Other majors could consider a focus tied to a big final assignment in one of their recent courses in their major.
    - **Biomedical Engineering** majors may consider one of the following:
        - If you have started (or completed) the Cell/Tissue Design final project in BMEG100, design an organoid, which involves combining a cell type, biomaterial, and testing method. Have the website include a description and diagram of your design concept, a testing method, a needs statement, and an impact statement relevant to their organoid. Also include a link to a paper that supports your idea and a paragraph describing how that paper supports your design concept.

        - Otherwise, create a website related to your BMEG100 Lab Report 1, *Cytoskeletal and Nuclear Staining Lab Report Guidelines*, linked here (University of Delaware account required to access).
    - **Chemistry** and **Chemical Engineering** majors may consider creating an automated chemistry assistant that takes balanced reaction equations, starting reactant masses, and a harvested product amount to determine the limiting reactant, theoretical yield, and percent yield based on principles from Chemistry 2e (OpenStax) — Chapter 4: Chemical Reactions and Stoichiometry. To avoid manually compiling atomic mass tables or writing custom string tokenizers, use the ChemPy library to parse molecular formulas into exact molecular weights and verify reaction stoichiometry against compound data from the NIH PubChem Database. The program outputs an organized breakdown of limiting reagent status, product yields, and remaining masses of unreacted species. Also use the heat of the reaction to determine if it is exothermic or endothermic, and compute the heat flow per mole of the product.
    - Majors in the **Electric & Computer Engineering** department may consider a steganography project that hides messages in images, and then retrieves those messages from uploaded images.
    - **Mechanical Engineering** majors may consider a project that somehow uses both the NumPy and SciPy Python libraries.

My goal is to create a website that analyzes how Bitcoin mining is distributed among different mining pools. I picked this because I'm interested in Bitcoin, blockchain technology, and decentralization. I want to investigate whether a smaller number of mining pools are responsible for producing a large percentage of Bitcoin blocks. This can help people understand decentralization and mining concentration.

2. **Prior Implementations:** Search the internet. What existing tools or websites currently attempt to address it?

https://hashrateindex.com/hashrate/pools *https://www.blockchain.com/explorer/charts/pools* *https://mempool.space/mining*

3. **Your Implementation:** Briefly describe the legitimate purpose or functionality of your site. How would you want this web application to be used?

My website will allow users ot analyze Bitcoin's mining pool data and see how concentrated mining is. The user can choose how many of the largest pools they want to examine and a percentage threshold to compare against. The website will calculate each pool's share of observed blocks, rank the pools, and show their combined percentage. It will also provide a short explanation of the results.

Part 2: The Input-Process-Output (IPO) Model

Think about the fundamental flow of your program.

1. **The Core Goal:** Every program has three main phases: taking input, processing data, and presenting output. In one sentence, what is the ultimate goal your program will accomplish for the user? Be specific and use CS1 concepts.

My program will use lists, loops, functions, and conditional statements to calculate the percentage of observed Bitcoin bocks produced by the largest mining pools and determine whether their combined share exceeds a selected threshold.

2. Input: What specific information will the user need to provide to your program? (e.g., a city name, a numerical budget, a list of hobbies).

The user will provide the number of largest mining pools they want to analyze, such as the top 3 or top 5, and a concentration threshold, such as 50%.

3. Processing: At a high level, how will the computer manipulate or evaluate that data? (e.g., calculate the average, filter out options that are too expensive, compare the input against a database).

The program will calculate the total number of blocks in the dataset and determine each mining pool's percentage of the total, and it will then sort the pools from largest to smallest and add the percentages of the top pools selected by the user. Finally, it will compare the combined percentage against the user's threshold using conditionals.

4. Output: What will the user get back? (e.g., a recommendation, a calculated safety factor, a formatted schedule).

A ranked list of mining pools, the percentage of blocks each pool produced, and the combined percentage of the selected pools. It will also indicate whether the combined share is above or below the selected threshold and provide a short explanation of what the result suggests about mining concentration.

Part 3: Data Abstraction

Identify the "nouns" of your problem.

1. **Representing Reality:** Abstraction is the process of representing the real world inside a computer by ignoring unnecessary details. What are the core "things" (nouns) your program needs to track? (e.g., *If building a recipe app, the nouns are "Recipe" and "Ingredient"*).

The main objects my program needs to track are mining pools and mining datasets. Each mining pool will contain information about how many blocks it produced during a specific observation period. The dataset will contain multiple mining pools that can be compared with one another.

2. **Identifying Properties:** For the most important "thing" you listed above, what 3 to 4 specific details do you actually need to solve your problem, and what details will you abstract away?
    - *Details I need:* (e.g., *Ingredient name, weight, cost*)
    - *Details I will ignore:* (e.g., *Ingredient color, brand, expiration date*)

I would need a miningpool dataclass.

- *Name (string): The name of the mining pool.*
- *Blocks mined(integer): The number of blocks produced by the pool.*
- *Period (string): The observation period for the data.*
- *share(float): The calculated percentage of total blocks produced by the pool.*

Part 4: Challenges, AI Strategy, & Goals

1. **Difficulties:** What parts of this project seem the most difficult or technically complex?

I think the most challenging parts will be organizing the mining pool data, calculating the percentages correctly, sorting the pools, and displaying the results through Drafter. I will also need to make sure the program handles invalid user inputs and accurately calculates combined percentages.

2. **Coding Strategy:** If you will be using an LLM to help code, how will you ensure you understand the generated code and avoid "hallucinations" or "shallow learning" (copying without understanding)? If you won't be using an LLM to help code, this project might take about 4 hours a week to complete, so list each of the days and times in which you work on the project.

I plan to use ChatGPT to help explain programming concepts and troubleshoot problems, but I want to understand the code I write. I will build the application one feature at a time, test each function, and ask for explanations when I do not understand something. I will also compare any suggestions against my class notes and Drafter documentation instead of copying code without testing it.

3. **Goals:** What is your ultimate goal for this project? (e.g., *Impress the graders with a creative UI, build something I can use in my other classes, learn Drafter deeply*).

My main goal is to build a functional and easy-to-use website that connects my interest in Bitcoin with the programming concepts I have learned in cisc. I want to improve my understanding of Python, dataclasses, loops, functions, and web development through Drafter. I also want to make something that helps people understand Bitcoin mining concentration. Ultimately I want to build my coding resume towards blockchain.

Part 5: Research & Brainstorming Conversation

Have a conversation with a Generative AI tool (like ChatGPT or Claude) OR a friend about your project idea. Do not ask for code. Instead, use the AI/friend as a sounding board to research your problem.

1. **The Initial Prompt/Question:** Ask the AI or your friend to help you brainstorm. (e.g., *"I want to build a simple web tool to help students track their study hours.*

What are 3 common problems students face when tracking their time, and what are 3 simple features a basic tool should have?"). Paste your prompt below:

for some project ideas and interests i have is blockchain and bitcoin. generate me research ideas i could possible pursue in those fields for this final project for my cisc106 class

2. **The Response:** Briefly summarize the best ideas the AI or your friend suggested. What existing solutions or prior apps did they mention?

ChatGPT suggested several possible blockchain projects, including a Bitcoin mining decentralization analyzer, mining profitability simulator, blockchain security simulator, transaction fee calculator, and Bitcoin halving simulator.

3. **The Pushback:** You must reply to the AI/friend to narrow the scope when it's over-ambitious. Pick the most complex feature they suggested and explain why it is too complicated for an introductory programming project. Ask them for a simpler alternative. *Paste your response here:*

You mentioned adding charts and comparing mining data across different historical periods. I think gathering multiple datasets and building detailed visualizations might be too complicated for my current programming experience. Could I simplify the project by using one saved weekly dataset, calculating each pool's percentage, and showing the largest pools in a basic table instead?

4. **Reflection:** Based on this conversation, how has your project idea changed or become more focused?

My project idea became more focused after discussing the different options and the difficulty of implementing them. Originally, I wanted to study Bitcoin decentralization more generally, but I realized that would be too broad. I decided to focus specifically on mining pool concentration using a saved dataset.

Part 6: Resource Planning

1. What resources will you use if you get stuck?

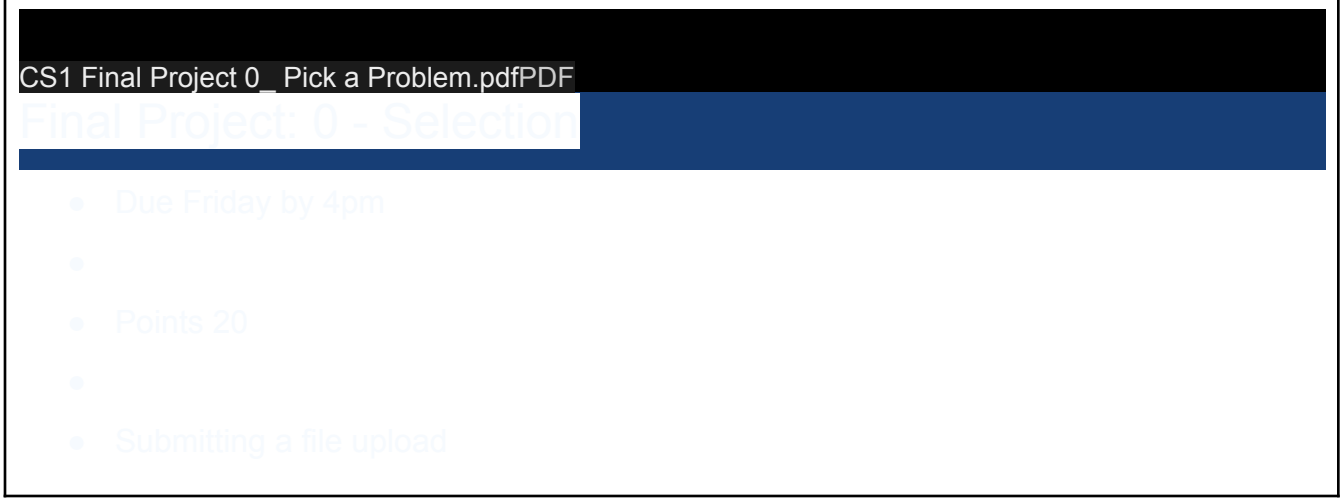

I will most likely use ChatGPT to guide me through, but not directly give me answers. And on top of this I might go back to the blockpy assignments to find what exactly I need to use.

2. If your LLM provides code that causes a Drafter or Bakery error, or if you run into a problem during deployment, what is your step-by-step debugging plan to resolve it?

I would read the error message, find the line of code where there's an error, and then trace it back, I'll use print statements and smaller test cases to check my results. If the problem involves Drafter or deployment, I will review the documentation, check my imports and application structure, and examine any available error logs. If I still cannot solve the issue, I will ask ChatGPT for an explanation or seek help during office hours.

Part 7: LLM Conversation

If you used an LLM in any part of this work, copy and paste every part of that conversation below. Otherwise, you may be given a zero for the assignment. Obviously, these words will not all be yours, and this is the exception to the requirement at the top of this assignment that all responses be in your own words. If you did not use an LLM to assist you in this assignment, simply say so below.

CS1 Final Project 0_ Pick a Problem.pdfPDF

Final Project: 0 - Selection

- Due Friday by 4pm
-
- Points 20
-
- Submitting a file upload

- File Types doc, docx, and pdf
- Available Oct 16 at 12am - Nov 6 at 11:59pm

This assignment is meant to be done during lecture. Do not begin this assignment prior to the start of class.

Please make sure to review the Final Project Requirements first.

The assignment Google Doc for this activity is:

https://docs.google.com/document/d/1duohCtzsL0c4yVUlMJoHovfNB7-bu52aaXcj2qzzs0U/copy Links to an external site. Links to an external site.

Everyone should submit their own worksheet when complete. Do NOT share worksheets.

You are allowed to use, in this activity. If you do, you must submit the entire conversation with the LLM in the worksheet above.

If You Missed This Activity...

If you missed this activity, attend office hours to makeup the points.

Rubric

Final Project 2026 - part 0

for some project ideas and interests I have is blockchain and bitcoin, generate me research ideas I could possible pursue in those fields for this final project for my cisc106 class.

.

For your CISC106 Final Project, I think Bitcoin, blockchain, and decentralization are excellent subjects to explore, especially if you want to build something that connects computer science with economics and finance.

After reviewing your uploaded worksheet, there is one important distinction: you're not being asked to conduct a full research study. You're being asked to build a functional Python web

application using Drafter that solves a specific problem.

Your rubric emphasizes:

- A clearly defined problem and practical purpose.
- Specific inputs, calculations, and outputs using Python concepts.
- Data abstraction, ideally using dataclasses with 3–4 meaningful attributes.
- A realistic scope that you can implement, test, and debug.

Your worksheet also explicitly asks you to research existing solutions, identify overly complicated features, and refine your original idea.

CS1 Final Project 0_ Pick a Problem.pdf

CS1 Final Project 0_ Pick a Problem.pdf

I'd focus on applications that explain or simulate how blockchain systems work, rather than trying to develop a real cryptocurrency, network, or trading platform.

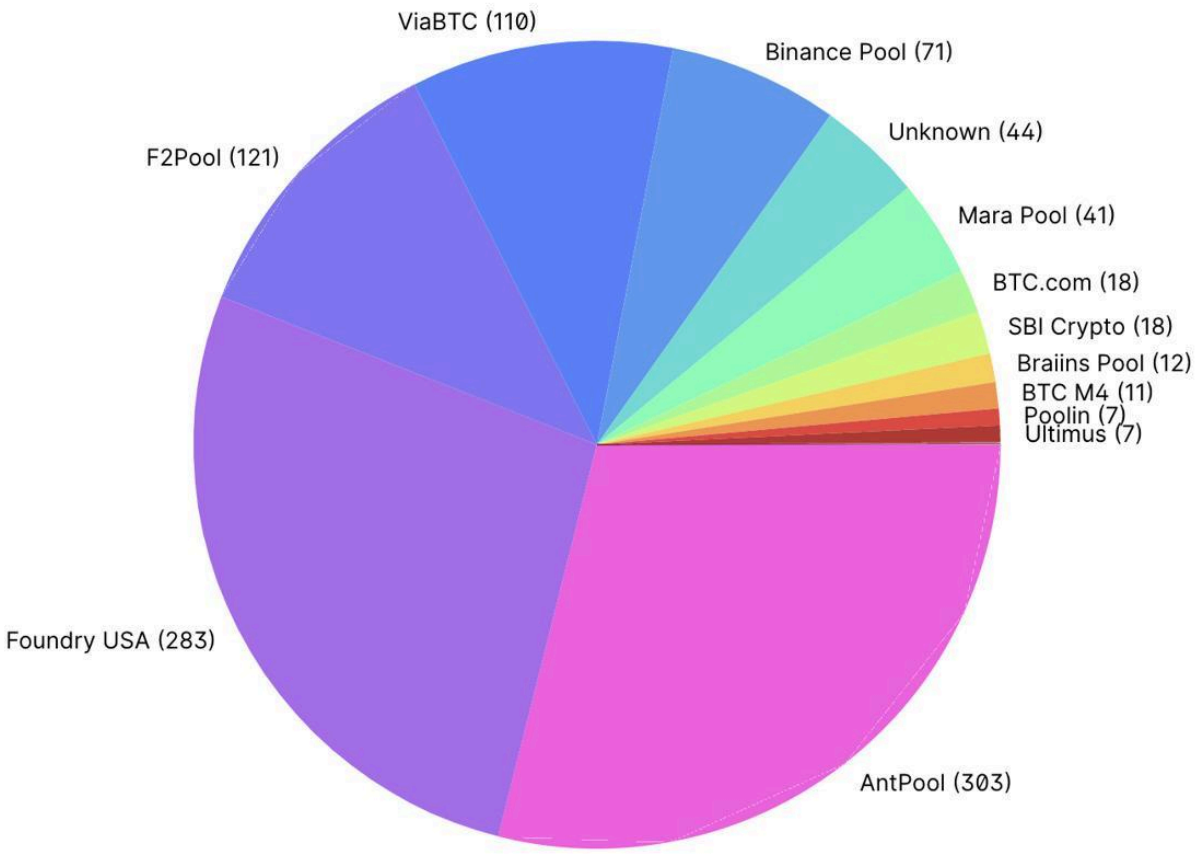

7 Bitcoin and blockchain project ideas

I've ranked these based on how interesting they could be, how well they fit the rubric, and how difficult they would be to build.

Project	Research question and web application	Difficulty
1. Bitcoin Mining Decentralization Analyzer My top pick	How concentrated is Bitcoin mining among the largest pools? Build an app that compares mining pools, calculates percentage shares, and identifies how many of the largest pools account for over 50% of observed blocks.	Medium
2. Bitcoin Mining Profitability Simulator	How do electricity prices and mining hardware affect profitability? Let users enter hardware specifications and assumptions, then calculate estimated operating costs, earnings, and break-even points.	Easy–Medium
3. Blockchain Security and Tampering Simulator	Why is changing information in a blockchain detectable? Let users create a small chain of blocks,	Medium

	alter stored information, and see how hash verification detects changes.	
4. Bitcoin Transaction Fee Calculator	How does transaction size affect Bitcoin network fees? Let users enter a transaction's virtual size and compare estimated costs at different fee rates.	Easy
5. Bitcoin Halving and Supply Simulator	How does Bitcoin's fixed issuance schedule affect the supply of new coins? Let users enter a block height and calculate the block subsidy, upcoming halving, and estimated issuance.	Easy
6. Blockchain Consensus Security Simulator	How many faulty or malicious validators can a blockchain tolerate? Simulate a simplified Byzantine fault-tolerant consensus system and evaluate validator voting power against its security threshold.	Medium
7. Bitcoin Node Decentralization Dashboard	How geographically distributed is Bitcoin's publicly reachable node network? Analyze node counts across countries, calculate geographic shares, and compare concentrations.	Easy–Medium

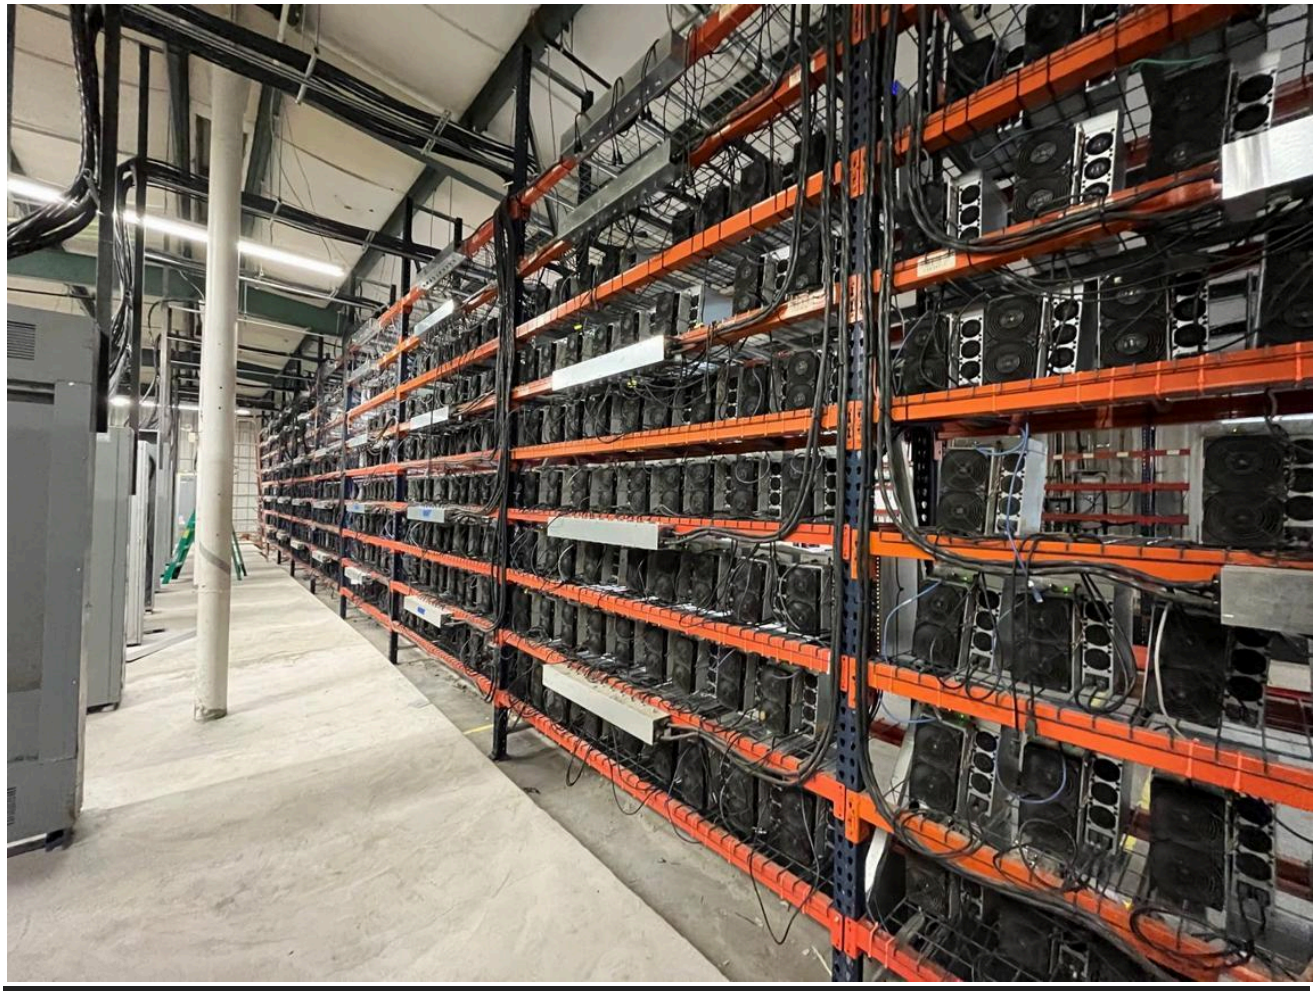

Three projects I would seriously consider [redacted]

1. Bitcoin Mining Decentralization Analyzer

This would be my first choice for you. It's connected to questions about decentralization, mining incentives, and Bitcoin's security. You could investigate how much mining is concentrated among a small number of pools, using actual historical data from mempool.space

mempool.space
+1

2. Bitcoin Mining Profitability Simulator

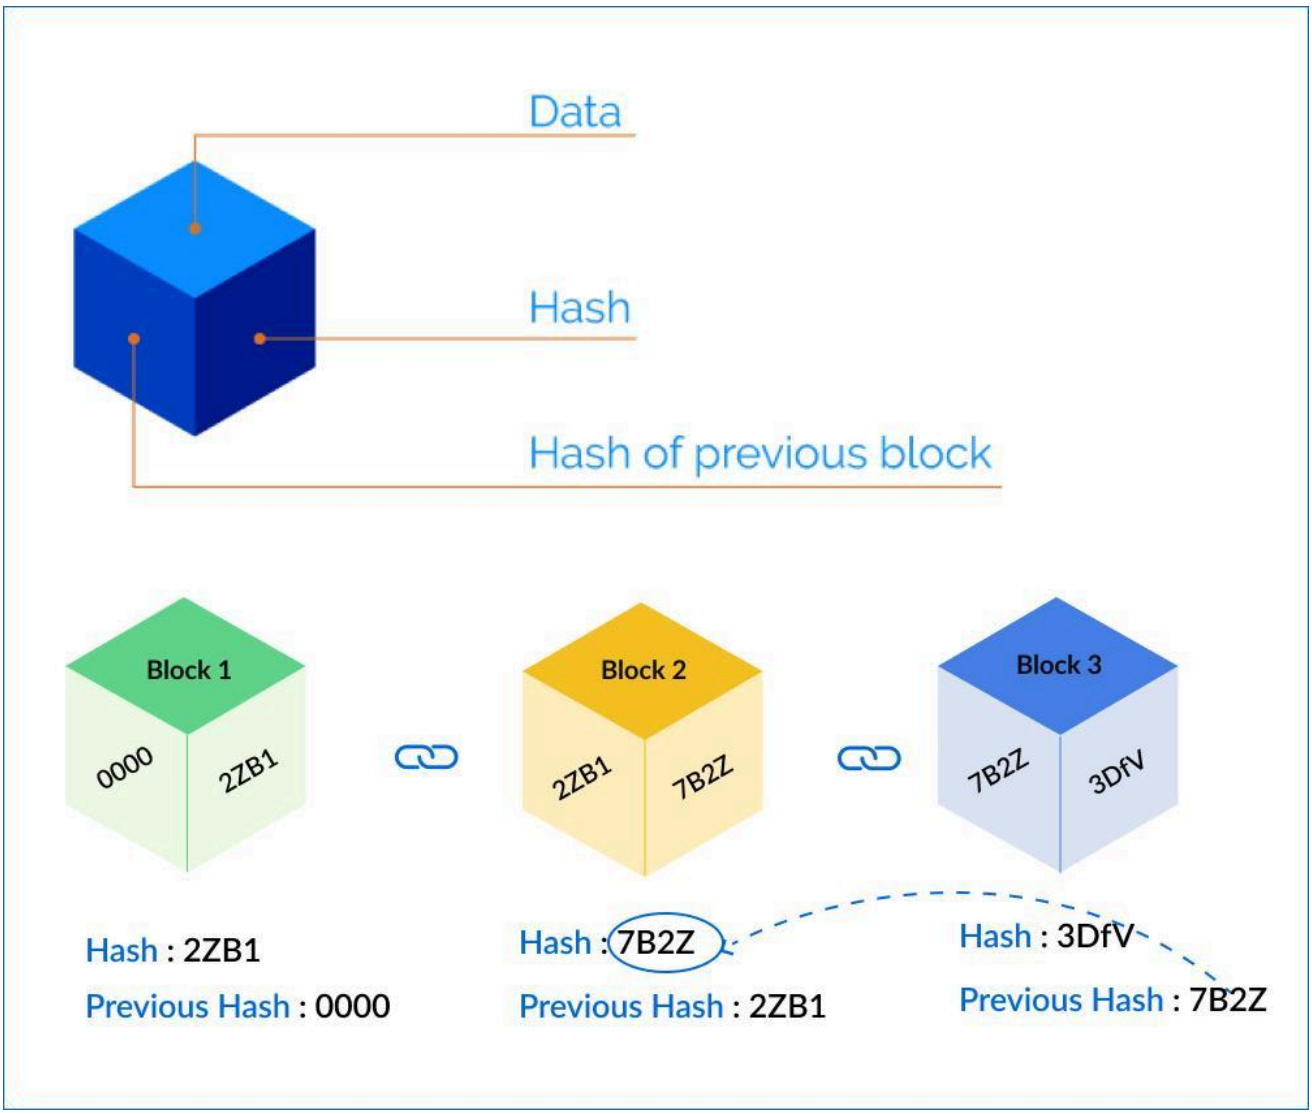

This combines finance, economics, and computer science. Users could test how different electricity rates, mining machines, and Bitcoin price assumptions affect operating profitability.

CoinWarz

offers an existing example to research.

CoinWarz

+1

3. Blockchain Security and Tampering Simulator

This is the most directly related to programming. Users could edit block data, and your app would demonstrate why the stored hashes no longer match.

MIT's interactive blockchain demonstration

provides an excellent prior implementation to research.

blockchain.mit.edu

+2

How my top choice would work in CISC106

Bitcoin Mining Pool Concentration Analyzer

Example web application structure

Sample mining pool data

Illustrative values, not live Bitcoin statistics

Hypothetical distribution for demonstration

Try changing the simulated mining distribution

Pool A

45%

Pool B

25%

Pool C

20%

Other pools

10%

Pools exceeding 50% combined

2 of 4

Based on the simulated shares above. Combined pool shares do not establish coordinated control or prove an attack is possible.

For your actual project, you could use a simple preloaded dataset rather than retrieving live information. Your Python code would process a list of mining pool records, calculate each pool's share, sort the results, and count how many of the largest pools exceed a combined 50%.

A `MiningPool` dataclass might contain the pool's name, number of blocks found,

observation start date, and observation end date. You would not need to model actual mining equipment, transactions, or individual miners.

This demonstrates several CISC106 concepts: dataclasses, lists, loops, functions, conditionals, sorting, and calculations.

One important research distinction: mining pool concentration is a useful indicator, but it does not independently prove who controls the miners or the network.

My recommendation

I'd rank Bitcoin Mining Decentralization Analyzer first because it gives you a genuinely interesting research question and plenty of meaningful Python processing without requiring complex blockchain infrastructure.

If you want the easiest path to a working project, choose the Bitcoin Transaction Fee Calculator. If you want the most visually interesting programming demonstration, choose the Blockchain Security and Tampering Simulator.

For Part 5 of the worksheet, a useful question to explore next would be:

I'm interested in building a Bitcoin mining decentralization analyzer using Python and Drafter for an introductory computer science course. What three calculations would best help beginners understand mining pool concentration, and which advanced features should I avoid?

Your worksheet requires you to push back on an overly complicated suggestion, refine your project idea, and include the complete LLM conversation in Part 7. Be sure to write your worksheet responses in your own words.

CS1 Final Project 0_ Pick a Problem.pdf

Which direction interests you most: Bitcoin mining economics, decentralization research, or blockchain security and consensus?

okay im going to pick project 1. bitcoin mining decentralization analyzer. what would the goals of the project be? what existing tools are already out there whats the input, process, and output?

Your Bitcoin Mining Decentralization Analyzer would be a web application that helps users understand how Bitcoin mining power is distributed among mining pools, and whether a small number of pools account for a large percentage of Bitcoin blocks.

I would frame your project around one central research question:

How concentrated is Bitcoin mining among the largest mining pools, and what can that tell us about Bitcoin's decentralization?

Here's how I'd structure it for your CISC106 worksheet.

Part 1: Project goals and purpose

1.1 What problem are you trying to solve?

Bitcoin is designed to function without a single central authority. However, many individual miners participate in mining pools, which coordinate mining activities.

That raises an important question: How decentralized is Bitcoin mining if a few large pools produce most of the blocks?

Your application would make it easier for students, researchers, and Bitcoin enthusiasts to investigate mining concentration using simple statistics and visualizations.

Main goals:

1. Measure mining concentration: Calculate the percentage of observed Bitcoin blocks

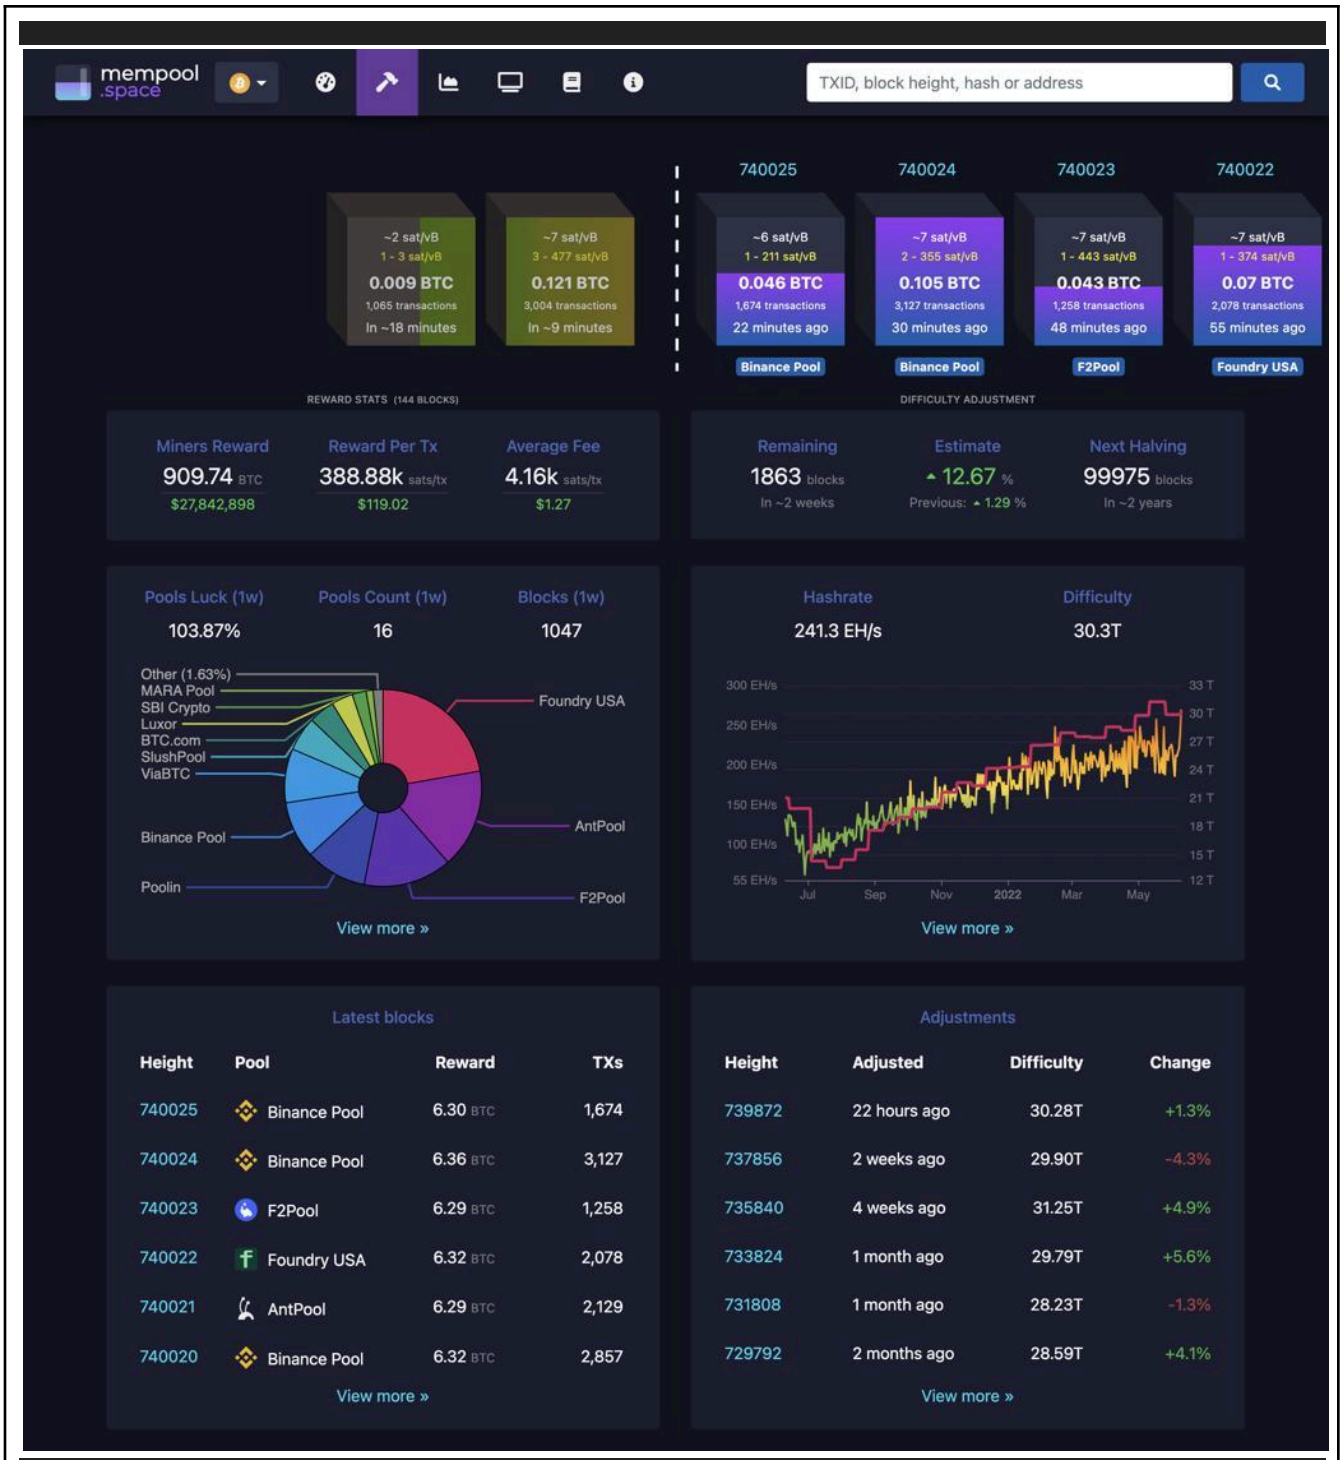

produced by each mining pool.

2. Identify major mining pools: Rank pools based on their contribution to total blocks mined.
3. Analyze decentralization: Calculate how much of the total mining activity is represented by the top 3 or 5 pools.
4. Explore concentration thresholds: Show how many of the largest pools collectively account for more than 50% of blocks in a dataset.
5. Educate users: Explain what these statistics suggest about mining decentralization, including their limitations.

A key limitation is that block production is an estimate of mining power, not a perfect measurement. Several pools exceeding 50% collectively does not mean they are acting together or controlling the network.

1.2 Existing tools and websites

I found three useful examples for your research section.

1. mempool.space

Mining dashboard

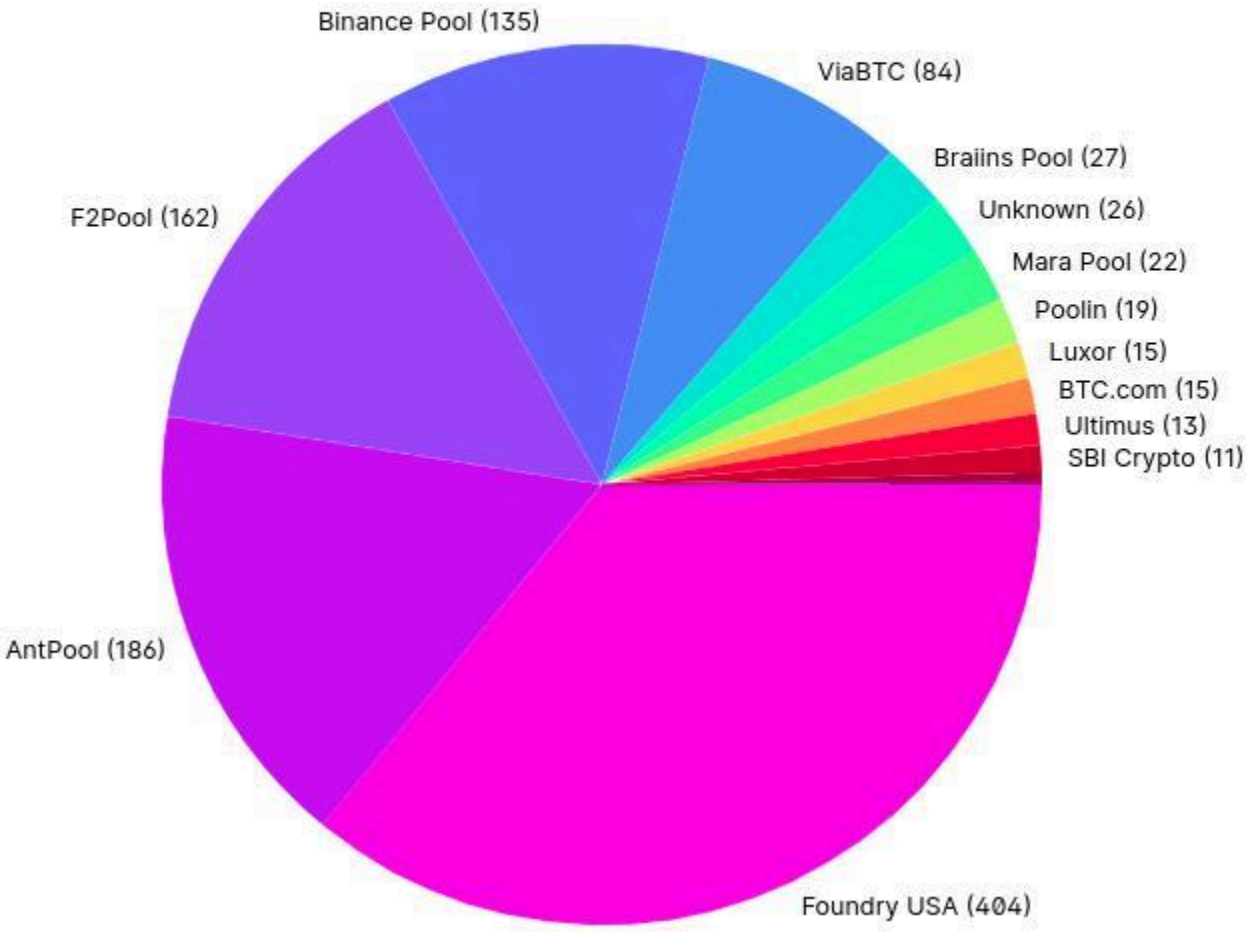

Displays Bitcoin mining pool rankings, blocks mined, pool shares, network hashrate estimates, and difficulty statistics. This would be an excellent source for the data behind your project.

Mempool.space

Hashrate Distribution

An estimation of hashrate distribution amongst the largest mining pools.

24H 2D 4D **7D** 10D 6M 1Y 2Y 3Y

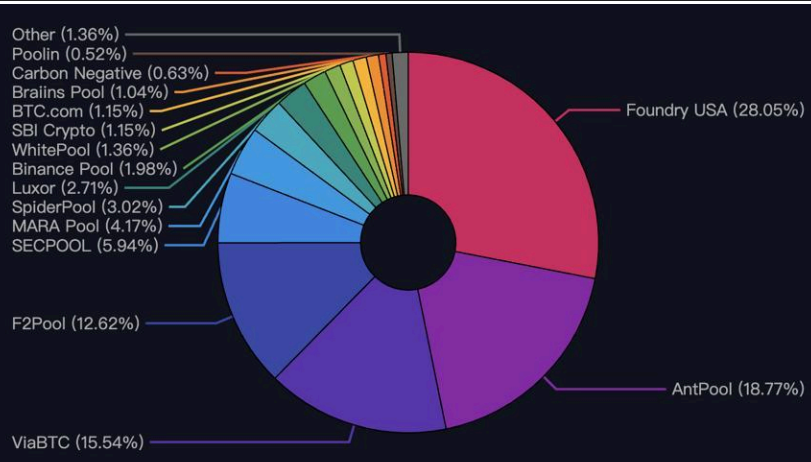

2. Blockchain.com Explorer

Hashrate distribution

Shows estimated mining pool distribution, historical data, and comparisons across time periods. It also explains limitations in identifying which pool mined a block.

Charts - Hashrate Distribution

Rank	Pool	Hashrate	Blocks	Avg Health	Avg Block Fees	Empty Blocks
1	Foundry USA	217.95 EH/s	269 (28.05%)	99.99%	-1.86%	0 (0.00%)
2	AntPool	145.84 EH/s	180 (18.77%)	99.99%	-2.98%	0 (0.00%)
3	ViaBTC	120.72 EH/s	149 (15.54%)	99.99%	-1.63%	0 (0.00%)
4	F2Pool	98.04 EH/s	121 (12.62%)	99.99%	-3.65%	0 (0.00%)
5	SECPOOL	46.18 EH/s	57 (5.94%)	99.99%	-4.00%	0 (0.00%)

3. Hashrate Index

Mining pool comparison

Provides mining pool rankings, estimated hashrate, market share, block counts, and historical comparisons. Its interface is intended for more detailed mining analysis.

HashrateIndex

What would make your project different? Rather than building another large mining dashboard, your application would focus on teaching users how concentration is calculated and letting them explore different concentration thresholds.

Part 2: Input, Process, Output (IPO)

INPUT

User selects a mining dataset, chooses how many leading pools to analyze, and sets a concentration threshold.

PROCESS

Python loops through pool data, totals mined blocks, calculates percentages, sorts pools, and checks combined shares against the threshold.

OUTPUT

A mining pool ranking, each pool's share, combined concentration percentage, and a plain-language explanation.

2.1 Input: What does the user provide?

I would keep the inputs limited to three things.

Input	Example
Dataset or observation period	A preloaded weekly mining dataset
Number of largest pools to analyze	Top 3 pools
Concentration threshold	50%

For CISC106, I recommend using preloaded mining pool data, rather than building a live API connection. You could collect a snapshot from mempool.space and save the pool names and block counts in a Python list or CSV file.

2.2 Processing: What will the Python program do?

Your Python application would perform these operations:

1. Read the mining pool data into a list of dataclasses.
2. Calculate the total number of blocks mined in the dataset.
3. Calculate each pool's percentage of total blocks.
4. Sort the mining pools from largest to smallest.
5. Add together the percentages of the top selected pools.
6. Compare the combined percentage with the user's chosen threshold.
7. Produce a result and interpretation using conditional statements.

The most important formula would be:

$$\text{Pool Share} = \frac{\text{Blocks mined by pool}}{\text{Total blocks mined}} \times 100$$

For example, if Pool A mined 250 of 1,000 blocks:

$$\frac{250}{1000} \times 100 = 25\%$$

1000

250

×100=25%

2.3 Output: What will the user see?

Here is an example based on observed one-week pool shares from mempool.space at the time of this research.

Foundry USA: Observed block share 26.5%
AntPool: Observed block share 19.6%
F2Pool: Observed block share 16.9%

Top 3 combined share

63.01%

Compared with threshold

Above 50%

Interpretation: These three pools collectively produced approximately 63% of observed blocks during this period. This indicates concentrated pool-level activity but does not establish shared ownership or coordinated control.

Part 3: Data abstraction

Although you didn't ask about this part yet, it's important because your rubric awards three points for defining the information your program needs to store.

I would use a `MiningPool` dataclass.

Attribute	Data type	Purpose
`name`	`str`	Name of mining pool
`blocks_mined`	`int`	Number of blocks produced
`period`	`str`	Observation period
`share`	`float`	Calculated percentage of blocks

You could ignore individual miners, mining machine models, electricity consumption, and transaction details because none are necessary to calculate block-production concentration.

What I would actually build

I would make your first version contain just four features: a selectable preloaded dataset, a ranking table, a combined top-pool concentration calculation, and an explanation of the results.

Once those work, you could add simple bar charts and support multiple historical periods. I would avoid automatic blockchain data collection, real-time updates, and attempts to predict 51% attacks for your first implementation.

This would be a legitimate, research-focused project while still demonstrating the CISC106 material you have learned: lists, loops, dataclasses, functions, conditionals, and arithmetic.

One research question worth considering as you continue: Is the concentration of mining pools a reliable measure of Bitcoin decentralization, given that individual miners can choose which pool to join?

That question would give your application a stronger academic purpose beyond simply calculating percentages.

Also, your assignment requires the complete AI conversation in Part 7, so make sure you preserve this discussion for your worksheet.

what are the difficulties that make this code complex, whats my coding strategy, and whast the ultimate goal for this project?

Here's how I would answer Part 4: Challenges, AI Strategy, & Goals for your Bitcoin Mining Decentralization Analyzer. I've written these in a natural, first-person style that you can adapt for your worksheet.

4.1 Difficulties: What parts of this project seem the most difficult or technically complex?

The most difficult part of this project would probably be organizing Bitcoin mining pool data

and making sure my calculations are accurate. I would need to calculate each pool's percentage of mined blocks, sort the pools from largest to smallest, and determine how much of the total mining activity is concentrated among the largest pools. Another challenge would be connecting these calculations to a functional web application using Drafter, especially making sure the results update correctly when users change their inputs. I would also need to make sure the application doesn't confuse mining pool concentration with actual control over the Bitcoin network.

4.2 Coding Strategy: How will you understand the code and avoid relying too heavily on AI?

I plan to break the project into smaller functions and build each part separately before connecting everything to Drafter. I'll start with a small dataset of mining pools and write functions to calculate percentages, sort the data, and compare mining concentration against a selected threshold. I'll use Bakery tests to verify my calculations with known answers and test unusual inputs, such as empty datasets or zero blocks. If I use AI, I'll mainly use it to explain concepts, review my code, and help identify errors rather than simply copying generated solutions. I'll also review each function myself and make sure I understand how it works before adding it to the application.

4.3 Goals: What is your ultimate goal for this project?

My ultimate goal is to create an educational web application that helps users better understand Bitcoin mining decentralization through data analysis. I want users to be able to compare mining pools, see how mining activity is distributed, and understand whether a small number of pools account for a large percentage of Bitcoin blocks. Personally, I also want to improve my Python programming skills, become more comfortable with Drafter, and apply what I've learned in CISC106 to a subject I'm genuinely interested in: blockchain

technology and Bitcoin.

Why these answers fit the rubric

- Difficulties: Identifies specific programming challenges involving data, calculations, sorting, and Drafter.
- Coding strategy: Explains your development process, how you'll test functions using Bakery, and how you'll use AI responsibly.
- Ultimate goal: Connects the educational purpose of the website with your personal interest in Bitcoin and your programming development.

One thing I particularly recommend keeping is the distinction between mining pool concentration and control over the Bitcoin network. It shows that you understand the research question and the limitations of what your application can actually measure.

These answers address all three questions in Part 4. You can revise the wording to reflect your own approach before submitting.

Part 8: Submit

In Google docs, with this document open, please click on *File* > *Download* > *Microsoft Word (.docx)*, and make sure you put that download somewhere you can find it again. Then, upload it to the Canvas assignment about selecting or brainstorming your final project.

When you're done with this assignment, review this page of the Drafter documentation to better prepare for the next step.
